A Conceptual Exercise Duality and Strong Duality Problem Prove that strong duality holds for a convex optimization problem with a strictly convex objective function and a relatively complete constraint set

Solution This proof leverages Slater's condition and the properties of convex functions. Slater's condition states that if the feasible set has a strictly feasible point (a point satisfying the inequality constraints strictly), then strong duality holds. A strictly convex objective function guarantees a unique optimal solution. The relatively complete constraint set ensures that the dual problem is feasible. Combining these, we can demonstrate the existence of a dual solution that achieves the same optimal objective value as the primal problem, thereby proving strong duality. This proof requires a thorough understanding of Lagrangian duality and convex analysis.

B Algorithmic Implementation Exercise Gradient Descent for Linear Regression Problem Implement gradient descent to solve a linear regression problem with L2 regularization (Ridge Regression). Analyze the effect of different step sizes on convergence speed and solution accuracy.

Solution The gradient descent update rule for Ridge Regression involves calculating the gradient of the objective function (sum of squared errors plus regularization term) and updating the model parameters iteratively. Different step sizes (learning rates) affect the algorithm's stability and convergence rate. A small step size leads to slow convergence but greater stability, while a large step size might accelerate convergence but risk oscillations or divergence. Empirical analysis comparing different step sizes on a chosen dataset allows for a practical understanding of these effects. This exercise involves coding skills and an understanding of gradient calculation.

C Application-Based Exercise Portfolio Optimization Problem Formulate a portfolio optimization problem that maximizes expected return subject to a constraint on the portfolio variance and individual asset weight constraints. Solve this problem using a quadratic programming solver.

Solution This involves expressing the expected return and portfolio variance as quadratic functions of the asset weights. The constraint on variance is a convex quadratic constraint. The individual asset weight constraints (e.g., nonnegativity, upper bounds on individual asset weights) are linear constraints. The entire problem can then be formulated as a convex quadratic program (QP), which can be efficiently solved using specialized QP solvers available in optimization libraries like CVXOPT or SciPy. This exercise requires understanding portfolio theory and the ability to translate financial concepts into a mathematical optimization model.
